A series of problems lead to limits and derivative, here are 2 examples:

- **tangent line**: use **secant line** to approach tangent line
- **instantaneous velocity**: use **average velocity** in a shorter period time to estimate instantaneous velocity

## 1 Limit of a Function

### 1.1 Definition of Limit

Limit of a function is written as

$$\lim_{x \rightarrow a} f(x) = L$$

it means that the limit of  $f$  as  $x$  approaches  $a$  equals  $L$ . Note that the limit has nothing to do with  $f(a)$ .

### 1.2 Term Approach

- informally, approach means getting closer to a certain value
- formally definition will be introduced latter

### 1.3 One-Sided Limits

For left-hand limit:

$$\lim_{x \rightarrow a^-} f(x) = L$$

For right-hand limit:

$$\lim_{x \rightarrow a^+} f(x) = L$$

Note that

$$\lim_{x \rightarrow a} f(x) = L$$

exists only when both left-hand and right-hand side limits exist.

### 1.4 Infinite Limits

Let  $f(x)$  is defined on  $(a - \delta, a) \cup (a, a + \delta)$ ,

$$\lim_{x \rightarrow a} f(x) = \infty$$

leads to infinite limits. Note that:

- here  $\infty$  can be either  $+\infty$  or  $-\infty$
- it often occurs when the function is not defined at  $x = a$  or  $a$  is pole of ration functions

## 1.5 Vertical Asymptote

The line  $x = a$  is called a vertical asymptote of  $y = f(x)$  if

$$\lim_{x \rightarrow a, a^+ \text{ or } a^-} = \infty$$

natural log has a vertical asymptote  $x = 0$  since

$$\lim_{x \rightarrow 0^+} \ln x = -\infty$$

## 2 Limit Laws and Theorem

### 2.1 Limit Laws

Suppose  $f$  and  $g$  are two functions and  $c$  is a constant:

1. **sum:**  $\lim(f + g) = \lim f + \lim g$
2. **difference:**  $\lim(f - g) = \lim f - \lim g$
3. **constant multiplication:**  $\lim(cf) = c \lim f$
4. **product:**  $\lim(fg) = (\lim f)(\lim g)$
5. **quotient:**  $\lim(f/g) = \lim f / \lim g$ , if  $\lim g \neq 0$

From the laws above, the following laws can be obtained:

- **power:**  $\lim f^n = (\lim f)^n$
- **limit of constant:**  $\lim c = c$

### 2.2 Direct Substitution Property

If  $f$  is a polynomial or rational function and  $a$  is in the domain of  $f$ , then

$$\lim_{x \rightarrow a} f(x) = f(a)$$

In fact this property is true if the function is **continuous** at  $x = a$ .

### 2.3 A Useful Fact

If  $f(x) = g(x)$  when  $x \neq a$ , then

$$\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} g(x)$$

provide the limit exists, this is very useful to get the limit of a ration function whose pole that can be canceled by its numerator factor.

## 2.4 Limit Theorems

- **two sides theorem:**  $\lim_{x \rightarrow a} f(x) = L$  if and only if

$$\lim_{x \rightarrow a^+} f(x) = \lim_{x \rightarrow a^-} f(x) = L$$

- **comparison theorem:** if  $f(x) \leq g(x)$  and both function have limits at  $x = a$ , then

$$\lim_{x \rightarrow a} f(x) \leq \lim_{x \rightarrow a} g(x)$$

- **squeeze theorem:** if  $f(x) \leq g(x) \leq h(x)$  and

$$\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} h(x) = L$$

then

$$\lim_{x \rightarrow a} g(x) = L$$

## 3 Precise Definition of Limit

Let  $f$  be a function defined on some open interval that contains the number  $a$  except possibly at  $a$  itself. Then we say the limit of  $f$  as  $x$  approaches  $a$  is  $L$ :

$$\lim_{x \rightarrow a} f(x) = L$$

if for every number  $\epsilon > 0$  there is a number  $\delta > 0$  such that

$$|x - a| < \delta \implies |f(x) - L| < \epsilon$$

Comment: range constrain leads to domain constrain.

### 3.1 Precise Definition of Left Hand and Right Hand Limit

Similar way can be applied to these 2 definitions:

- **Left-Hand Limit:**

$$\lim_{x \rightarrow a^-} f(x) = L$$

if for every number  $\epsilon > 0$  there is a number  $\delta > 0$  such that

$$a - \delta < x < a \implies |f(x) - L| < \epsilon$$

- **Right-Hand Limit:**

$$\lim_{x \rightarrow a^+} f(x) = L$$

if for every number  $\epsilon > 0$  there is a number  $\delta > 0$  such that

$$a < x < a + \delta \implies |f(x) - L| < \epsilon$$

### 3.2 Precise Definition of Infinite Limit

Let  $f$  be a function defined on some open interval that contains the number  $a$  except possibly at  $a$  itself. Then

$$\lim_{x \rightarrow a} f(x) = +\infty$$

if for **every** positive number  $M$  there is  $\delta > 0$  such that

$$|x - a| < \delta \implies f(x) > M$$

Similar definition can be applied to negative infinite limit.

## 4 Continuity of Functions

### 4.1 Definition

A function  $f$  is continuous at number  $a$  if

$$\lim_{x \rightarrow a} f(x) = a$$

this indicate 3 conditions:

- $f(a)$  is defined at  $a$
- limit of  $f$  at  $a$  exists
- limit equals to  $f(a)$

A function is continuous on an interval if it is continuous at every number in the interval. Also a function can be either continuous from left or right.

### 4.2 Types of Discontinuity

There are 3 types:

- **removable**: one point problem
- **infinite**: reach infinity at certain point
- **jump**: left limit doesn't equal to right limit

### 4.3 Theorems of Continuity

- if  $f$  and  $g$  are continuous at  $a$  and  $c$  is a constant, then  $f \pm g$ ,  $cf$ ,  $fg$ ,  $f/g$ , where  $g \neq 0$  are also continuous at  $a$
- polynomials are continuous on  $\mathbb{R}$
- any rational function is continuous wherever it is defined (denominator is not zero)
- the following function are continuous everywhere in their domains: polynomials, rational function, root, trig, inverse trig, exponential, logarithmic functions.

- if  $f$  is continuous at  $b$  and

$$\lim_{x \rightarrow a} g(x) = b$$

then

$$\lim_{x \rightarrow a} f(g(x)) = f\left(\lim_{x \rightarrow a} g(x)\right) = f(b)$$

- if  $g$  is continuous at  $a$  and  $f$  is continuous at  $g(a)$ , then  $f \circ g$  is continuous at  $a$
- **intermediate value theorem**: suppose  $f$  is continuous on interval  $[a, b]$  and let  $N$  be any number between  $f(a)$  and  $f(b)$  where  $f(a) \neq f(b)$ , then there exist a number  $c \in (a, b)$  such that  $f(c) = N$ , this is the foundation for finding root of polynomial  $P(x)$  in  $(a, b)$  if  $P(a)P(b) < 0$

## 5 Limits at Infinity and Horizontal Asymptote

The line  $y = L$  is called a **horizontal asymptote** of the curve  $y = f(x)$  if either

$$\lim_{x \rightarrow \infty} f(x) = L \quad \text{or} \quad \lim_{x \rightarrow -\infty} f(x) = L$$

Example:

$$\lim_{x \rightarrow -\infty} \tan^{-1} x = -\frac{\pi}{2} \quad \text{and} \quad \lim_{x \rightarrow \infty} \tan^{-1} x = \frac{\pi}{2}$$

Here is one useful theorem: if  $r > 0$  is a rational number, then

$$\lim_{x \rightarrow \infty} \frac{1}{x^r} = 0$$

If  $x^r$  is defined for all  $x$ , then

$$\lim_{x \rightarrow -\infty} \frac{1}{x^r} = 0$$

And here is the precise definition for **bound limit** as  $x$  reach infinity: let  $f$  be a function defined on some interval  $(a, +\infty)$ , then

$$\lim_{x \rightarrow \infty} f(x) = L$$

means that for every  $\epsilon > 0$ , there is a corresponding  $N$  such that if  $x > N$ , then

$$|f(x) - L| < \epsilon$$

similar definition works for  $x$  approaches  $-\infty$ . For **unbound** limit as  $x$  reach infinity: let  $f$  be a function defined on some interval  $(a, +\infty)$ , then

$$\lim_{x \rightarrow \infty} f(x) = \infty$$

means that for every positive number  $M$  there is a corresponding number  $N$  such that if  $x > N$ , then  $f(x) > M$ .

## 6 Derivatives and Rate of Change

### 6.1 Tangent Line

The tangent line to the curve  $y = f(x)$  at point  $P(a, f(a))$  is the line through  $P$  with **slope**

$$m = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a}$$

provided that this limit exists.

### 6.2 Velocity

- velocity can be considered as slope of position function
- acceleration can be considered as slope of velocity function

### 6.3 Derivative

The derivative of a function  $f$  at a number  $a$ , denoted by  $f'(a)$ , is

$$f'(a) = \lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h} = \lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a}$$

the tangent line to  $y = f(x)$  at  $(a, f(a))$  is the line through  $(a, f(a))$  whose slope equals to  $f'(a)$ . And derivative can also be considered as instantaneous rate of change of a function at certain value.

## 7 Derivative as Functions

The derivative of function  $f$  is defined by:

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

here is some common alternative notation:

$$f'(x) = y' = \frac{dy}{dx} = \frac{df}{dx} = \frac{d}{dx} f(x) = Df(x) = D_x f(x)$$

A function is differentiable at  $a$  if  $f'(a)$  exists and it is differentiable on an open interval  $I$  if it is differentiable at every number in the interval.

### 7.1 Differentiable vs Continuous

If  $f$  is differentiable at  $a$  then it is continuous at  $a$ , the reverse may not be true. Meaning differentiability requires a **higher** condition than continuity.

### 7.2 Function Fail to be Differentiable

- a sharp corner,  $y = |x|$
- discontinuity,  $y = 1/x$
- vertical tangent,  $y = \sqrt[3]{x}$

### 7.3 Higher Derivative

The derivative of a function is a function, which may have its own derivative.

- second derivative:  $f''$
- third derivative:  $f'''$

Example:

- **velocity** is the (first) derivative of position function
- **acceleration** is the second derivative of position function
- **jerk** is the third derivative of position function

## 8 Extra

### 8.1 Greatest Integer Functions

It is defined as:

$$y = f(x) = \lfloor x \rfloor$$

- piece-wise function
- continuous from right side

### 8.2 Triangle Inequality

It states that:

$$|a + b| \leq |a| + |b|$$
